

recessed portion shaped to fit a pointed head portion of a device.

## ABSTRACT OF THE DISCLOSURE

The interface between a first substrate and light-emitting diodes formed on the first substrate is selectively irradiated with an energy beam and transmits the energy beam through the first substrate, thereby selectively releasing the light-emitting diodes. The light-emitting diodes are then transferred onto a device holding layer included on a device holding substrate. Subsequently, the light-emitting diodes are transferred onto a second substrate. The irradiation of the interface with the energy beam enables the devices to be easily released from the first substrate.
